**Abstract**

The objective of this study was to detect the AmpC producing organisms in the urine samples. The urinary tract infected samples were collected and processed on various agar media and identified by observing colony morphology followed biochemical tests. In 212 urine samples growth of bacteria was only seen in 63 (29.71%) samples which were identified as the \textit{Escherichia coli} and 149 (70.28%) samples which found to be healthy. Antimicrobial susceptibility testing was performed using the Kirby-Bauer disk diffusion method with the following set of antibiotics: Ampicillin/ Sulbactum (10/10 µg/disc), Aztreonam (30 µg/disc), Cefepime (50 µg/disc), Cefpodoxime (10 µg/disc), Ceftazidime (30 µg/disc), Cephaloridine (30 µg/disc), Ciprofloxacin (10 µg/disc), Imipenem (10 µg/disc), Meropenem (10 µg/disc), Ofloxacin (2 µg/disc), Piperacillin/Tazobactam (100/10 µg/disc), Tigecycline (15 µg/disc) and Pazufloxacin (5 µg) to detect extended spectrum beta lactamase on all 63 \textit{E. coli} isolates. As per CLSI guidelines extended spectrum beta lactamase production was determined by the presence of augmentation towards the cephalosporins. AmpC was detected by flattening of the zone of Ampicillin/Sulbactum towards Ceftazidime. All were resistant to cefotaxin and sensitive to cefepime. AmpC beta-lactamase production was confirmed in 5 (50%) isolates of the 10 positive isolates obtained by the AmpC detection test. Hodge test was done on all AmpC producers obtained by AmpC detection test.

**Introduction**

It is imperative that risk factors for infections due to extended spectrum beta-lactamase (ESBL) producing organisms be clearly identified so that effective strategies to limit outbreaks of these infections may be developed. Several studies have attempted to elucidate risk factors for infections due to ESBL-producing organisms, but the results have been widely disparate [1]. ESBLs cause bacterial resistance to the penicillins, first, second and third-generation cephalosporins, aztreonam by hydrolysis of these antibiotics and are inhibited by clavulanic acid [2]. Bacterial infections of Human Immunodeficiency Virus (HIV) patients increase the rate of morbidity and mortality among those patients because of the defects in both the cell-mediated and humoral immunity [3]. Detection of ESBL production and AmpC-lactamases in organisms from urine samples may be important because this represents an epidemiologic marker of colonization and play an important role in the selection of appropriate therapy [4]. Currently numerous such enzymes are known and more continued to be described. Of particular clinical and epidemiological importance is AmpC beta lactamasases capable of inactivating the effects of broad spectrum cephalosporins and penicillins [5]. The first bacterial enzyme reported to destroy penicillin was the AmpC beta lactamase of \textit{Escherichia coli}, although it had not been so named in 1940 [6]. Swedish investigators began a systematic study of the genetics of penicillin resistance in \textit{E. coli}. Mutations with stepwise enhanced resistance were termed ampA and ampB [7]. A mutation in an ampA strain that resulted in reduced resistance was then designated AmpC [8]. Beta lactamases production by several gram negative and gram positive organisms is perhaps the most important single mechanism of resistance to penicillins and cephalosporins. It was surprising to find cephaparin resistant \textit{Klebsiella} species among the clinical isolates [9-11]. Standard disk diffusion breakpoint for cefotaxin (zone diameter <18 mm) to screen isolates and used a 3 dimensional extract test as a confirmatory test for isolates that harbour AmpC beta lactamas [12]. Moreover, the 3 dimensional test was modified, being made user friendly to be applied as a phenotypic screening method for detection of AmpC harbouring gram negative organisms [13]. The detection of bacteria in clinical samples is important in diagnosing various diseases therefore it is necessary to collect and examine samples at various time intervals [14]. The genital discharges of asymptomatic women with infertility problems are characterized by a prevalence of \textit{Gardnerella vaginalis} (19.7%), Enterobacteriaceae or Enterococci (12.1%) and \textit{Streptococcus agalactiae} (8.6%) [15]. \textit{Enterobacteriaceae} members are among the most frequently and easily transferrable bacterial species responsible for severe HAI [16]. The study showed moderately high frequency of AmpC \(\beta\)-lactamase producing \textit{E. coli} which may increase morbidity and mortality among children. Earlier detection of AmpC \(\beta\)-lactamases will decrease the morbidity rate of AmpC \(\beta\)-lactamase producing \textit{E. coli} infection.

**Materials and Methods**

**Sample collection**

This study was carried out in the microbiology laboratory of Sree Amman Arts and Science College Chitide Erode, Tamil Nadu during the period of November 2014 to March 2015. A total of 212 urine samples were collected in sterile containers (5 ml bottle) form female of age 16 to 35 various admitted in the hospitals around the Erode District and brought to Microbiology Laboratory and stored at 4°C for the further study.

**Processing of urine samples**

Urine samples were characterized for the physical appearance and followed by microscopic examinations for the presence of expected isolates.
Culturing methods

After sample collection they were processed on Blood agar, Mac Conkey’s agar and Eosin methylene blue agar media. These media were prepared, sterilized and inoculated with urine samples. Then the culture plates were incubated at 37°C for 24 hours. After incubation, colonies obtained on solid media were studied further for identification by microscopic and biochemical method. AmpC detection and antibiotic susceptibility were done by conventional methods.

Microscopic examination

The microscopic examination such as Hanging drop method, Gram staining, Flagella staining and Capsule staining were performed for identification of isolates.

Biochemical characterization

The isolates were biochemically identified via Indole test, Methyle red test, Voges Proskauer test, Citrate test, Triple sugar iron test, catalase test and urease test by following [17].

Carbohydrate fermentation

The fermentation broth (with a specific carbohydrate such as glucose, manitol, lactose, sucrose, sorbitol and cellulobiose) was prepared and poured into the fermentation tubes containing Durham’s tubes in an inverted position without any air bubble and sterilized at 121°C for 15 minutes. After sterilization the isolates were added to the fermentation broth and incubated at 37°C for 24 hours. After incubation result were noted for the colour changes in the fermentation broth.

Antimicrobial susceptibility test (Kirby-Bauer disk diffusion method)

Antimicrobial susceptibility test was determined by Kirby-bauer’s disc diffusion method as per [18]. For this test, Mueller- Hinton agar plates were prepared. Sterile cotton swabs were dipped in the culture broth and then soaked swabs were rotated against the upper inside wall of the tube to remove excess fluid. The entire agar surface of the plate was streaked with the swab three times, turning plate at 60 degree angle between each streaking. The medium was allowed to dry for 60 minutes. Using antibiotic disc dispense following discs were released on to the surface. The antimicrobial discs used were ampicillin/sulbactum, aztreonam, cefepime, cefpodoxime, cefazidime, cefoxitin, ciprofloxacin, imipenem, meropenem, ofloxacin, piperacillin, tazobactum, tigecyclin and pazufloxacin. The discs were pressed down with sterile bacteriological loop to secure. The plates were placed in the center of the test area. The plate was incubated overnight at 35 ± 2°C in ambient air for 16-24 hours. Quality control of the antibiotic discs were performed according to CLSI guidelines. Quality control of the following organisms MHT Positive Klebsiella pneumoniae ATCC1705 and MHT Negative Klebsiella pneumoniae ATCC1706 were run with each batch of the test. After 24 hrs, MHT Positive test showed a clover leaf-like indentation of the Escherichia coli 25922 growing along the test organism growth streak within the disc diffusion zone. MHT Negative test showed no growth of the Escherichia coli 25922 along the test organism growth streak within the disc diffusion.

Results

Sample collection

A total of 212 urine samples were collected from various hospitals around the Erode district of Tamil Nadu. Out of 212 urine samples were studied, growth of bacteria was obtained in 63 (29.71%) urine samples and no growth were found in 149 (70.28) samples they found to be healthy. The infected patients were found to be the 16 to 31 years old.

Physical character of urine samples

Total number of urine samples that were studied was 212 and out of them 63 samples showed bacterial growth. The colour of urine was yellow bearing acidic hydrogen ion concentration.

Identification of isolates

The urine samples observed for gram staining were found gram negative rod shaped bacteria. Urine isolates were found motile bacteria in hanging drop method. Under capsule staining it was observed capsulated bacteria. In flagella staining it was found that bacteria beared flagella.

Colony morphology

Urine isolates produced lactose fermenting smooth pink colored colonies on Mac Conkey agar (Figure 1A) that indicated ability to ferment the lactose in the medium. In Blood agar non hemolytic colonies were seen (Figure 1B) that indicated it did not lysis the red blood cells. In Eosin methylene blue agar it was observed as blue-black with a metallic sheen (Figure 1C). These all characters belong to Escherichia coli.

Biochemical characterization

The isolates were biochemically identified by showing indole positive, methyl red positive, Voges Proskauer negative, citrate negative, TSI there was no acid formation or gas formation in the slant and butt thus no hydrogen gas was formed. In catalase test there was no any bubble formation that indicated negative result. In urease test...
Isolation and Identification of Antibiotic Mediated Resistant Betalactum Producing Escherichia coli from Urinary Tract Infected Patients in Erode District, Tamil Nadu, India.

Antibiotic sensitivity was determined using the Kirby-Bauer disk diffusion method with the following antibiotics: Ampicillin/Subactum (10/10 µg/disc), Aztreonam (30 µg/disc), Cefepime (50 µg/disc), Cefpodoxime (10 µg/disc), Ceftazidime (30 µg/disc), Cefoxitin (30 µg/disc), Ciprofloxacin (10 µg/disc), Imipenem (10 µg/disc), Meropenem (10 µg/disc), Ofloxacin (2 µg/disc), Piperacillin/Tazobactam (100/10 µg/disc), Tigicycline (15 µg/disc) and Pazufloxacin (5 µg) to detect extended spectrum beta lactamase production on all 30 Escherichia coli isolates. The presence of AmpC beta-lactamases was suspected if there was no colour change in the medium that indicated the negative result. These all biochemical identification supported for Escherichia coli (Table 1).

Carbohydrate fermentation

The fermentation tests of specific carbohydrate such as glucose, manitol, lactose, sucrose, sorbitol and cellobiose after incubated at 37°C for 24 hours showed colour changes in the fermentation broth in all said carbohydrates except cellobiose (Table 1). Out of 64 urine isolates samples cultured, 30 were Escherichia coli, 14 were Klebsiella species and 20 belongs to other group.

ESBL detection

Antimicrobial susceptibility testing was performed using the Kirby-Bauer disk diffusion method with the following set of antibiotics: Ampicillin/Subactum (10/10 µg/disc), Aztreonam (30 µg/disc), Cefepime (50 µg/disc), Cefpodoxime (10 µg/disc), Ceftazidime (30 µg/disc), Cefoxitin (30 µg/disc), Ciprofloxacin (10 µg/disc), Imipenem (10 µg/disc), Meropenem (10 µg/disc), Ofloxacin (2 µg/disc), Piperacillin/Tazobactam (100/10 µg/disc), Tigicycline (15 µg/disc) and Pazufloxacin (5 µg) to detect extended spectrum beta lactamase on all 30 Escherichia coli. The fermentation tests of specific carbohydrate such as glucose, manitol, lactose, sucrose, sorbitol and cellobiose after incubated at 37°C for 24 hours showed colour changes in the fermentation broth in all said carbohydrates except cellobiose (Table 1). Out of 64 urine isolates samples cultured, 30 were Escherichia coli, 14 were Klebsiella species and 20 belongs to other group.

Discussion

Genes for AmpC beta-lactamases are commonly found on the chromosomes of the several members of the family Enterobacteriaceae, including Enterobacter, Shigella, and Providencia, Citrobacter freundii, Morganella morgani, Serratia marcescens and Escherichia coli [20,21]. Plasmid mediated AmpC beta-lactamases have arisen through the transfer of chromosomal genes for the inducible AmpC beta-lactamases to plasmids [22]. This transfer has resulted in plasmid mediated AmpC beta-lactamases in isolates of E. coli, Klebsiella pneumoniae, Salmonella species, Citrobacter freundii, Enterobacter aerogenes and P. mirabilis [23]. Plasmid mediated AmpC beta-lactamases represent a new threat since they confer resistance to cephamycins and are not affected by beta lactamase inhibitors, and can, in strains with loss of outer membrane porins, provide resistance to carbapenems [20,24]. This resistance mechanism has been found around the world, can cause nosocomial outbreaks, appears to be increasing in prevalence, and merits further study to define the best options for detection and treatment [25]. Although plasmid-mediated AmpC beta lactamases were first reported in the late 1980s, many infectious disease personnel remain unaware of their clinical importance [26]. The number of infections caused by AmpC producing organisms is increasing [27]. Distinguishing between AmpC- and ESBL-producing organisms has epidemiological significance and has therapeutic importance as well. Plasmid mediated AmpC beta lactamases from K. pneumoniae isolates was first reported in 1989 from Seoul, South Korea. From US, 6.9%
of K. oxytoca and 4% of Escherichia coli were AmpC producers [28]. The prevalence of AmpC beta lactamases in K. pneumoniae was 17.1%, E. coli 2% in China [29]. From North India, 47.8% E. coli, and 13% K. pneumoniae (Kolkata) were reported as AmpC beta lactamase producers [30]. From South Indian states, 24.1% of Klebsiella spp. and 37.5% of E. coli were AmpC producers from Chennai; In Karnataka, 3.3% of E. coli and 2.2% of K. pneumoniae were found to harbour AmpC enzymes. Of the 212 samples tested, 30 (14.15%) were E. coli and 14 (6.60) were Klebsiella species. Out of 30, 10 were extended spectrum beta lactamase producers. Extended spectrum beta lactamase producers were detected by Kirby-Bauer method [31]. Out of 10 ESBL positives, 5 were observed as AmpC producers by AmpC detection test. For the AmpC detection test cloxacillin containing media was used [32]. AmpC was detected by flattening of the zone of AmpCillin/Sulbactum towards Ceftazidime when compared to the earlier MHA plates [33]. Hodge test was done to confirm whether these isolates are AmpC producers or not and it is confirmed that 3 isolates were AmpC producers. A clear distortion of the zone of inhibition of cefotixin was observed in 3 isolates and this confirmed positive [34]. In the present study, 20% of AmpC producers were found. AmpC production in these isolates could be due a mechanism similar to that of extended spectrum beta lactamase producing organism that appear susceptible to ceftazidime by the disc diffusion method [35]. Cefotixin resistance in AmpC non-producers could be due to some other resistance mechanism such as, lack of permeation of porins. Inducible expression of chromosomal AmpC beta lactamas, although rare in E. coli and K. pneumoniae, is associated with a significant risk of therapeutic failure with all beta lactam drugs except carbapenems [36]. It was found that the sensitivity of the HODGE test is more when compared to AmpC Disc test. Hodge test is relatively easier to perform than compared to Disc test [37]. The highest percentage of AmpC-harbouring isolates in clinical specimens from admitted patients thus shows it nosocomial importance. AmpC beta lactamase producing bacterial pathogens may cause a major therapeutic failure if not detected and reported in time [13]. Thus the present study demonstrates the presence of AmpC β-lactamases producing bacteria in this region [38]. AmpC producing isolates have been commonly encountered in patients after prolonged hospitalization in ICU, following surgical procedures or those who had an underlying disease such as leukemia or who were immunocompromised. Therapeutic options for infections caused by Gram negative organisms expressing AmpC β-lactamas are limited because these organisms are usually resistant to all β-lactam antibiotics except for cefepime, ceptriome (4th generation cephalosporins) and carbapenems (Muna Mohammed and Fauzia Rajab 2014). This emphasizes the need for detecting AmpC β-lactamase harbouring isolates, so as to avoid therapeutic failures and nosocomial outbreaks [39-42].

Conclusion

In conclusion, this study has revealed the occurrence of AmpC beta-lactamase producing strains of Gram negative isolates in our region. Occurrence of a large percentage of multidrug resistant strains has been observed. AmpC beta-lactamase production is frequently accompanied by multidrug resistance, thus conjugative dissemination of these AmpC beta-lactamase encoding plasmids is thought to facilitate the spread of resistance against a wide range of antibiotics among different members of Enterobacteriaceae. Meropenem is superior to other antibiotics for the treatment of serious infections due to AmpC beta-lactamase-producing gram-negative bacteria.
